

# Original sketch of a capacitor QI thruster provided by Dr. Mike McCulloch

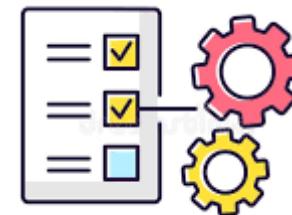

**Capacitor**, Aluminium foil

Separation = 7 micron

**Dielectric** between: kapton

Area of plates = 10x10cm

**Battery**. 1000V, a few  $\mu$ A.  
Can we pulse it?

**Our technical task:** to develop a remotely controlled high-voltage source that could be powered by a battery

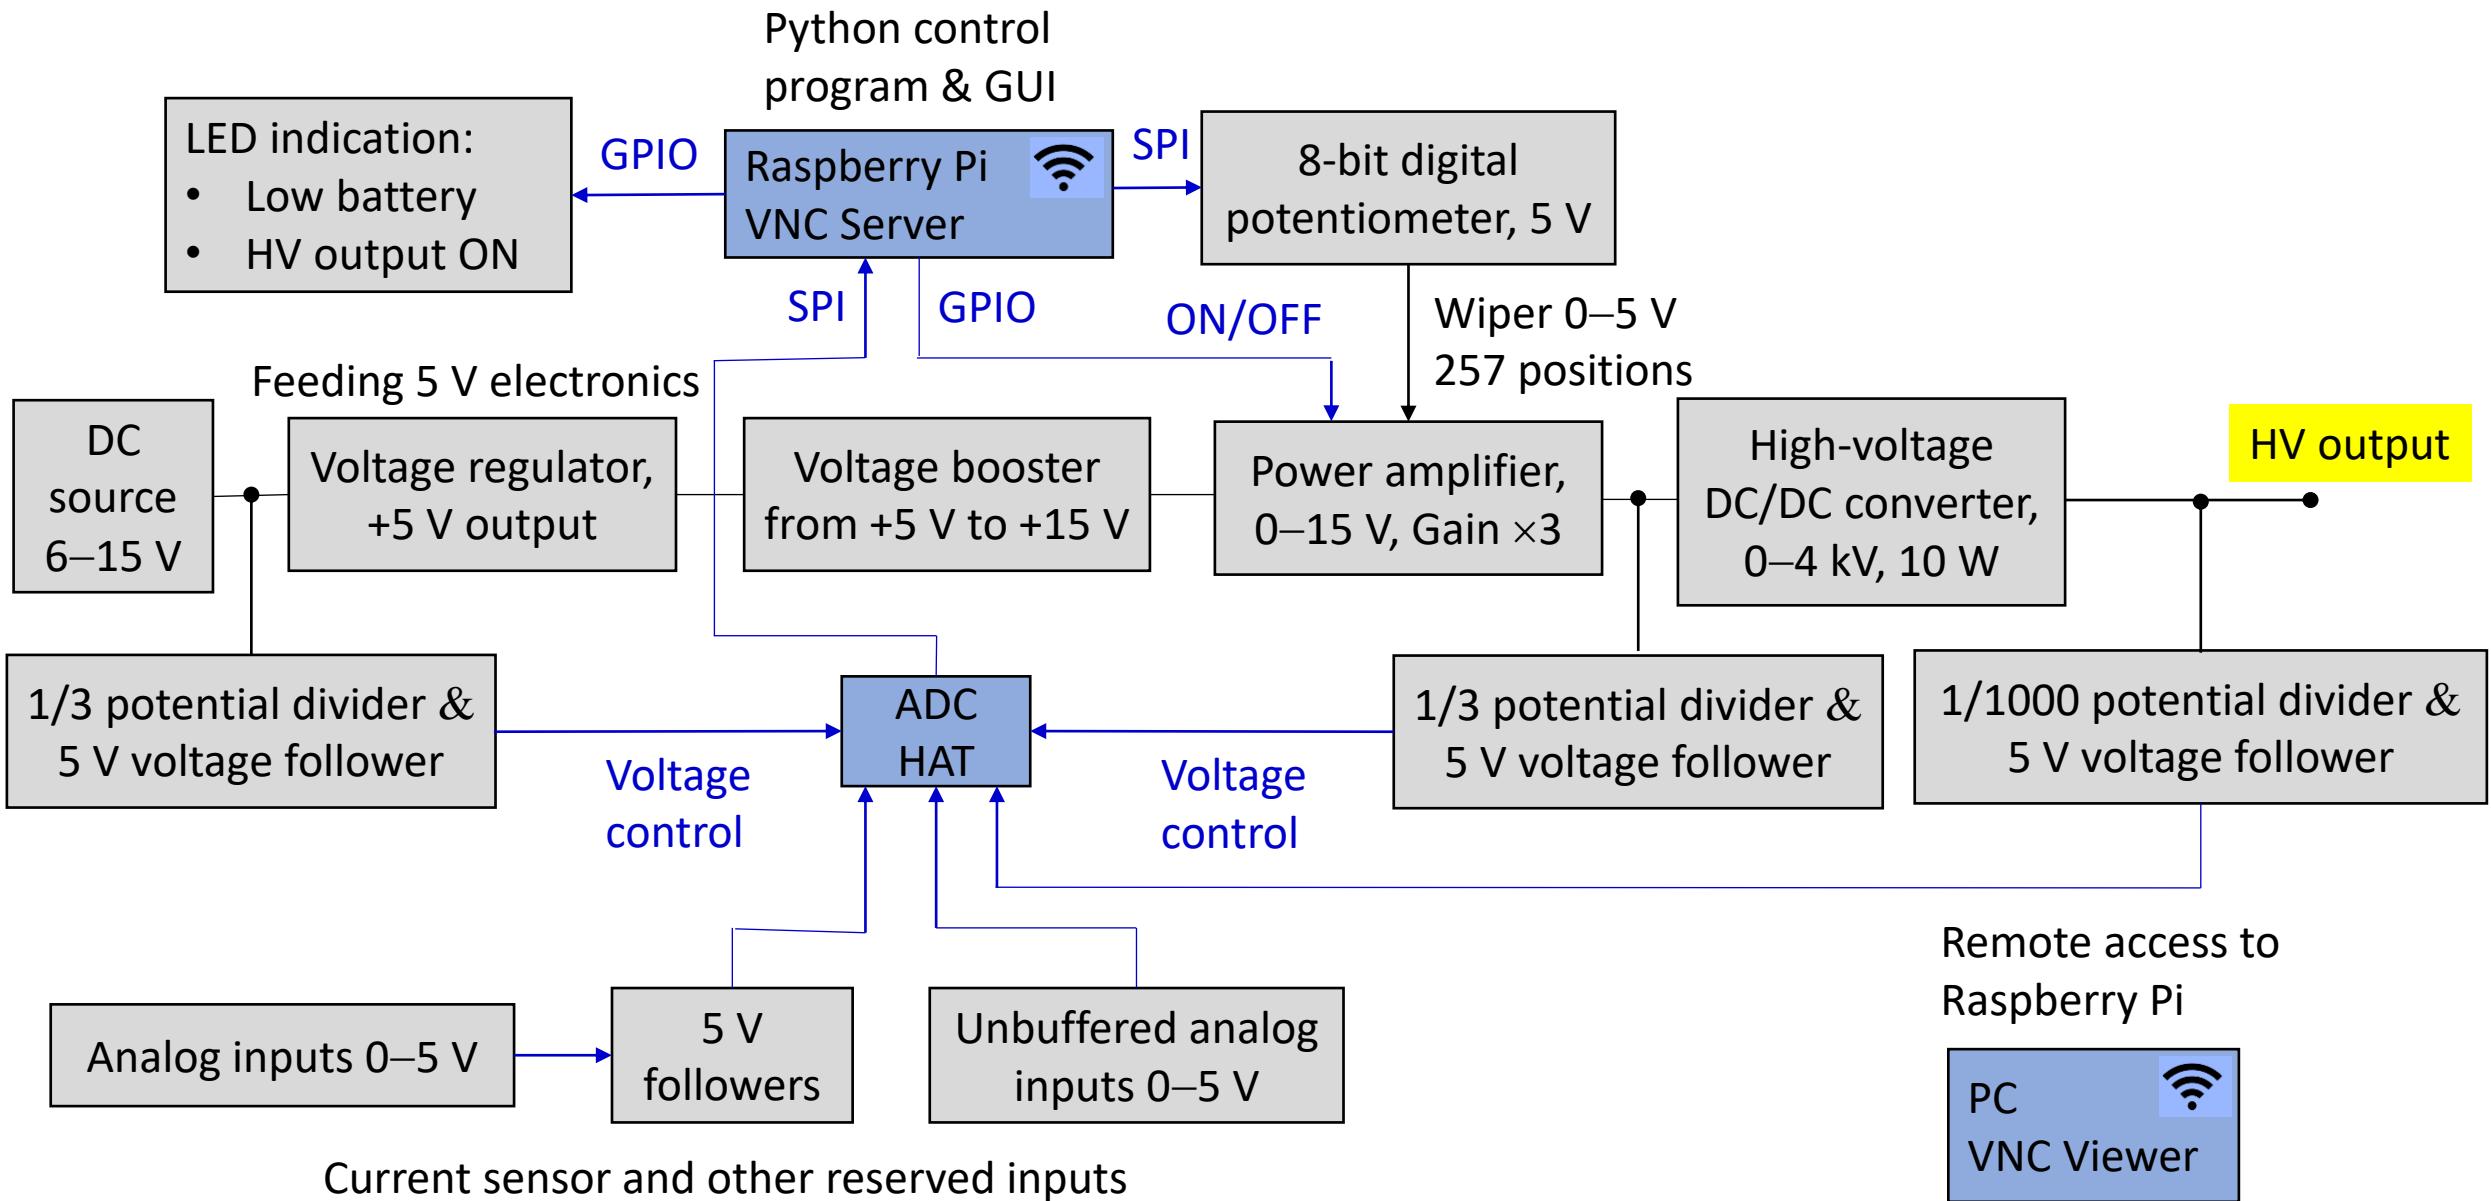

Digital Scales. Accuracy 0.1g. Capacity = 2kg

The force = 50mN. The mass change should be  $\sim$  5g.

$$F = \frac{0.00014IA}{d^2}$$

15.6 k (0.1%) sensor resistor

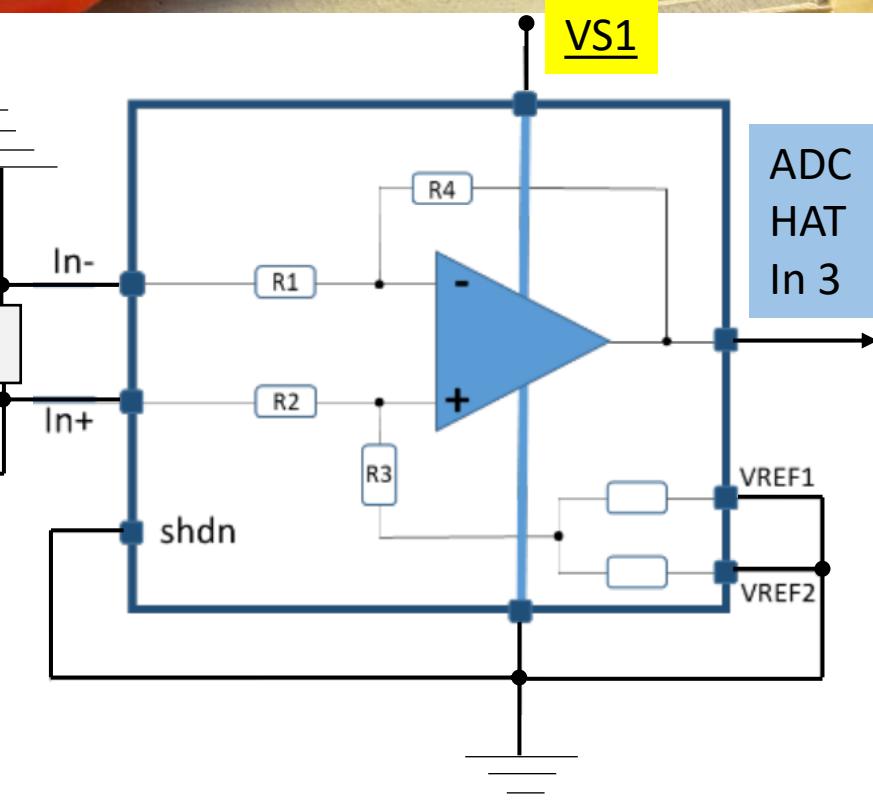

1.5 M HV series resistor

ADC HAT In 3

Low side sensing

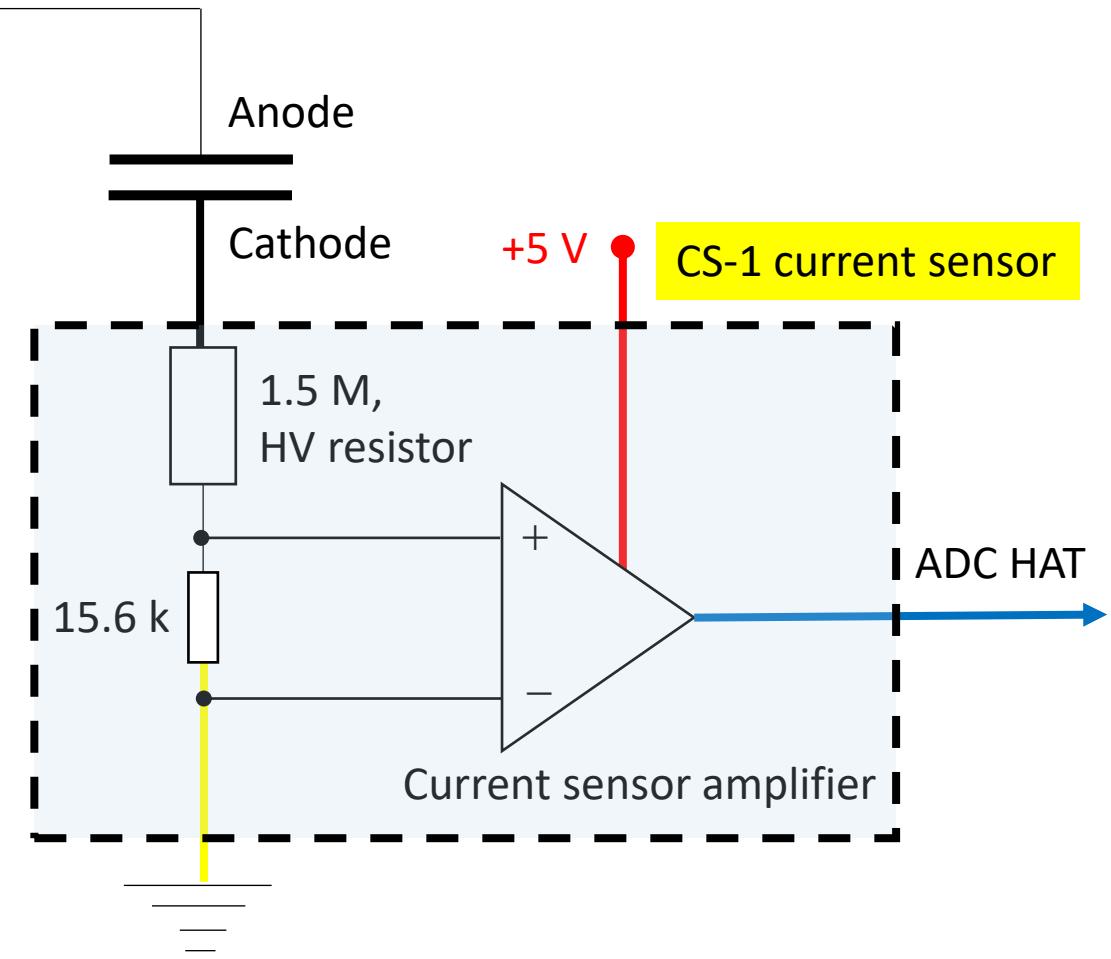

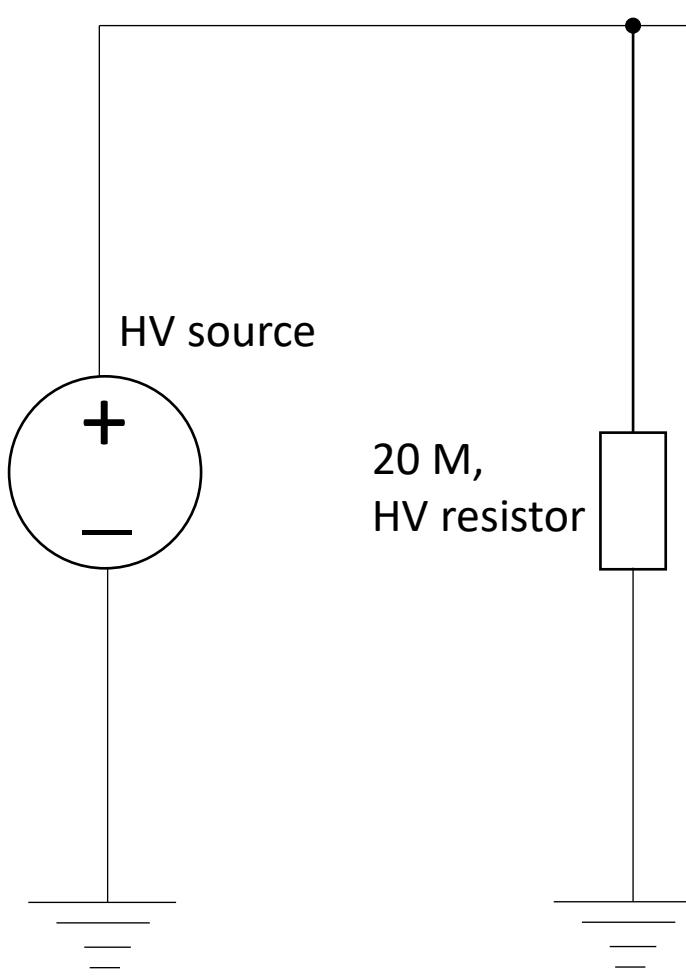

VO2 (0–4 kV, 2 mA)

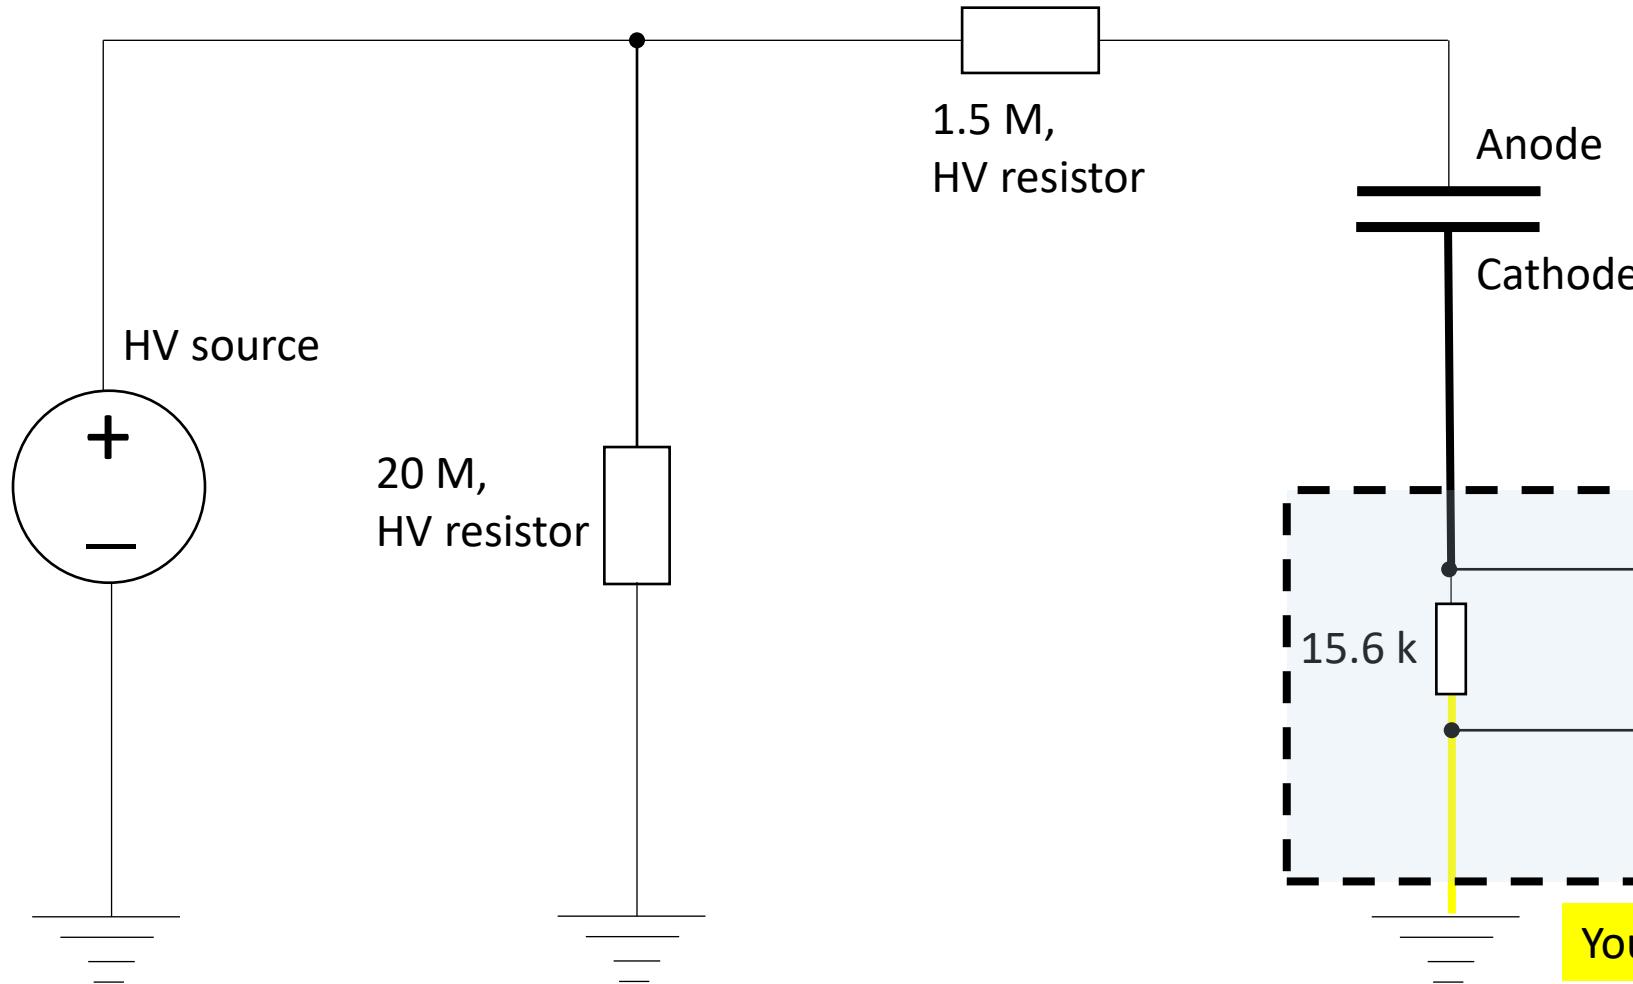

ADC  
HAT  
In 3

We connect the sensor output to ADC HAT In 3, which is unbuffered.

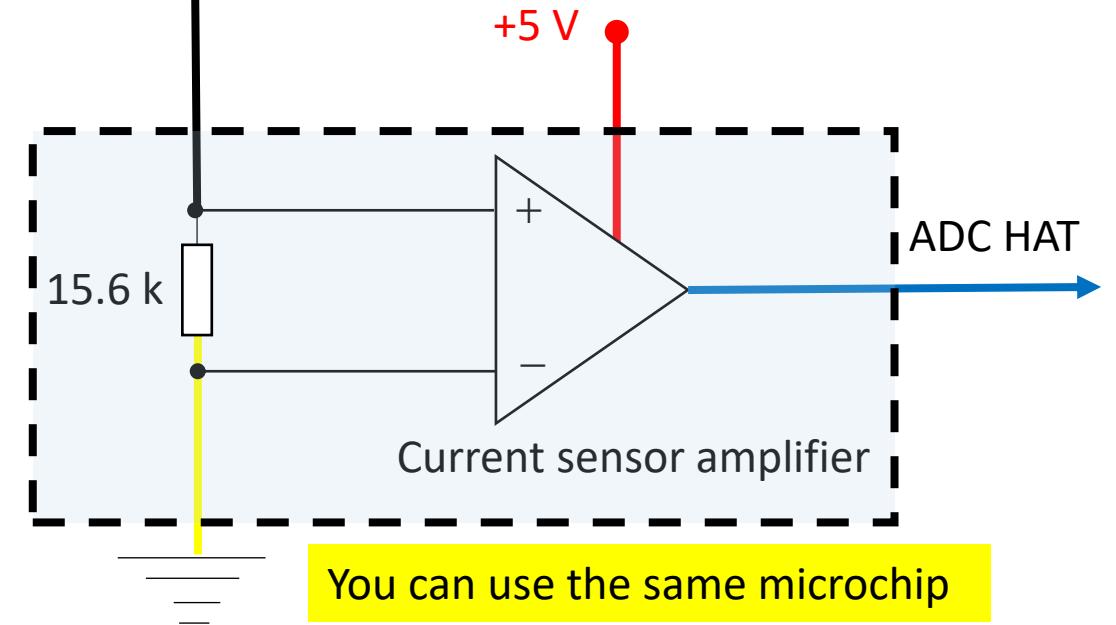

The sensor can also be connected to In 4 (unbuffered) or In 5, 6 (buffered).

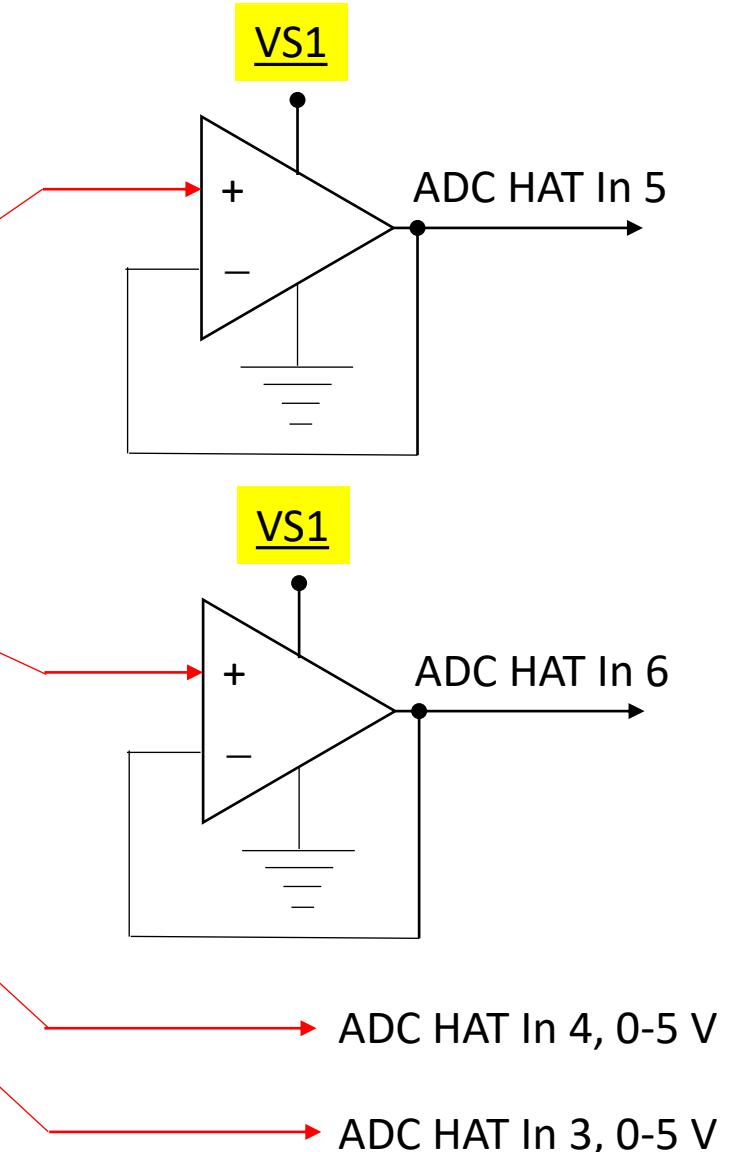

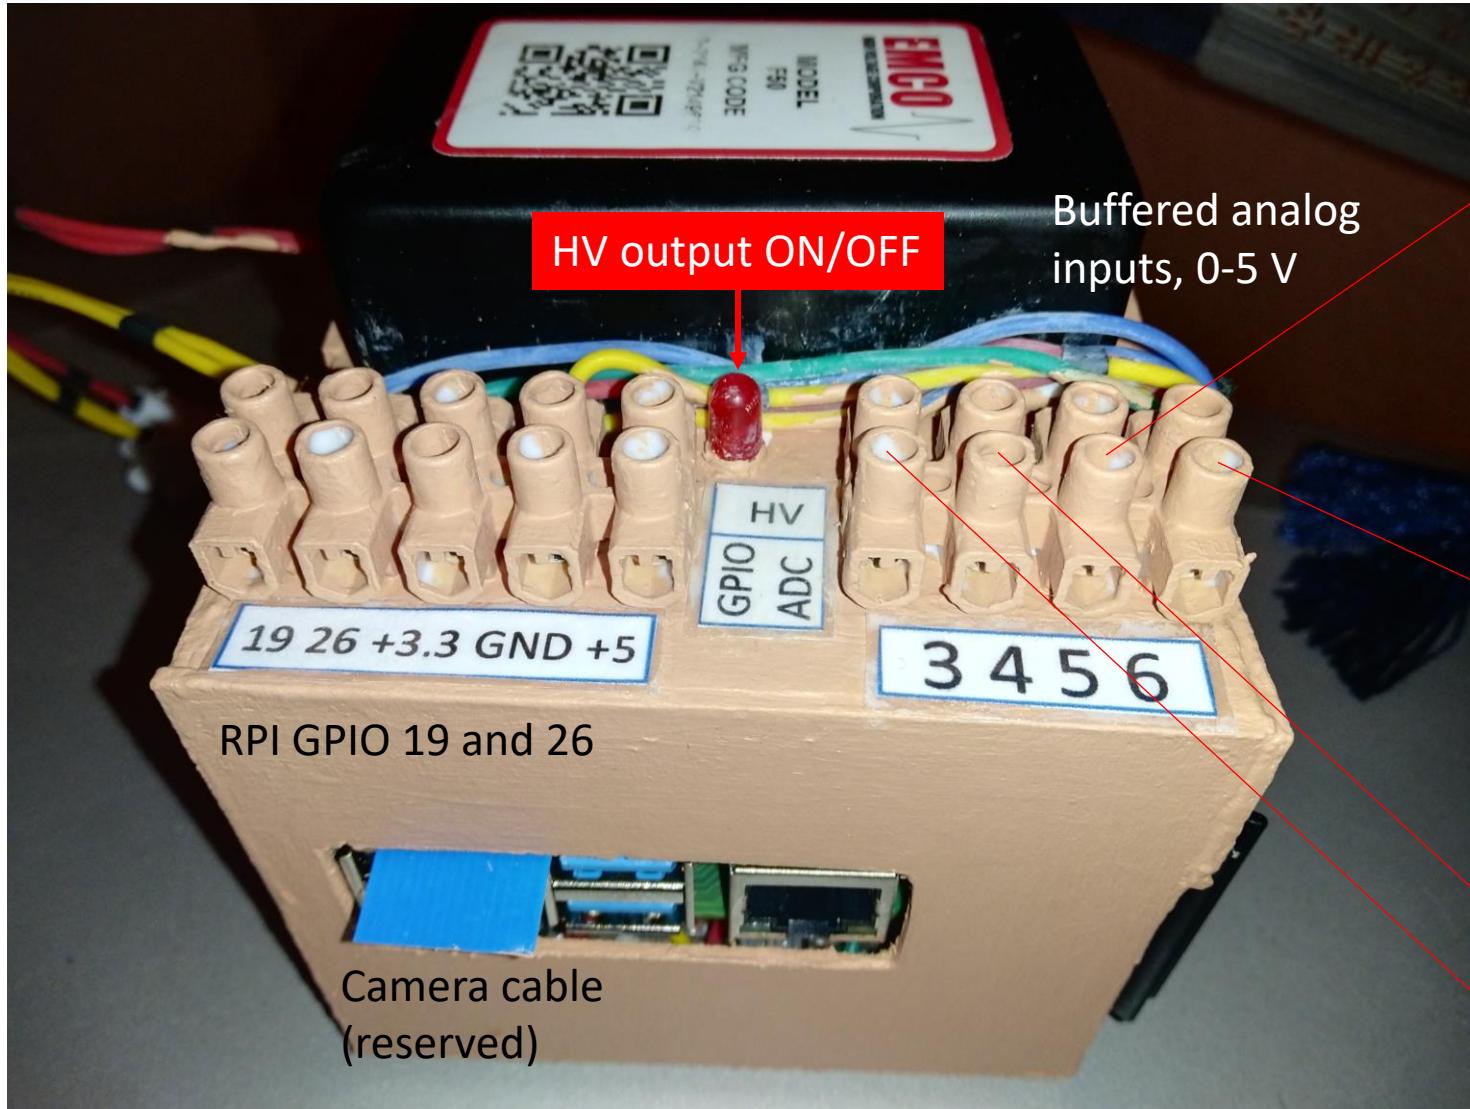

During dielectric breakdown, the capacitor cathode and the resistor network down to ground work as a current generator with a very large internal resistor  $1.5\text{ M}\Omega$  inside the sensor. This resistor limits the current and therefore may prevent “the avalanche”. That is why you may not hear “snaps”. You should explore other configurations, where a current limiting HV resistor is placed before the anode, while the low side sensor has only a  $\text{k}\Omega$  sensor resistor (next slide).

You should try this configuration  
 as well with a new current sensor  
 but without a large internal  
 resistor. Still use a current limiting  
 resistor before the anode.

# Device ports

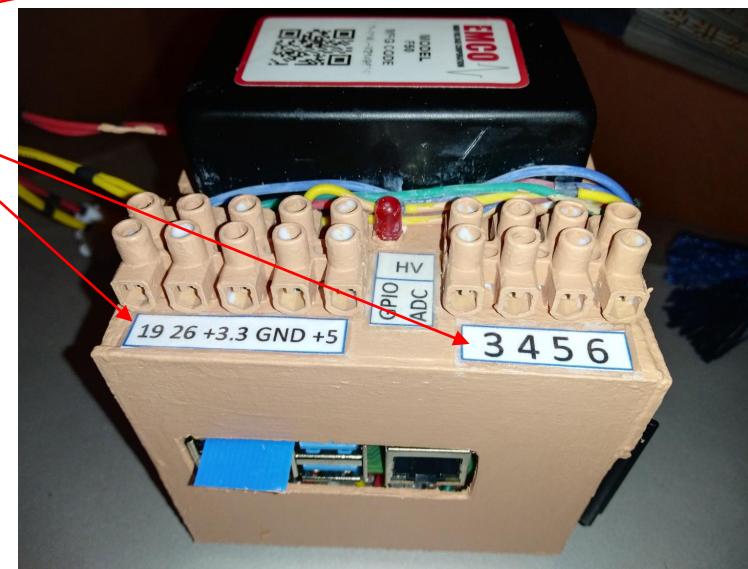

RPI GPIO 19 and 26 can be used, for example, for multiplexing the current sensor ranges in the future designs. This option has been already reserved for the current sensor function in the Python program.

# QI-1 interface without GUI. Run “main.py”.

```
1. # Measurement parameters (program inputs)
2. R_series = 1.5 # resistance in series with the QI capacitor in MOhms
3. R_shunt = 25.0 # shunting resistor across the QI capacitor in MOhms
4. C = 0.01 # estimated QI capacitance in uF (micro Farads)
5. factor_up = 5.0 # (factor_up * tau_up) is the waiting time for the capacitor full
charge
6. factor_down = 5.0 # (factor_down * tau_down) is the waiting time for the capacitor full
discharge
7. current_range = 1 # operational range of the current sensor; range 1 - GPIO 19, range 2
- GPIO 26
8. Ch = 3 # Your channel1 (ADC In 3 - In 6) for the current sensor. In 5 and 6 are
internally buffered.
9. # The current sensor function CurrentSensor(bias, Ch) is in Functions.py
```

```
1. def CurrentSensorRange(range):
2.     range1 = 19
3.     range2 = 26
4.     GPIO.setup(range1, GPIO.OUT)
5.     GPIO.setup(range2, GPIO.OUT)
6.     GPIO.output(range1, GPIO.LOW)
7.     GPIO.output(range2, GPIO.LOW)
8.     if range == 1:
9.         GPIO.output(range1, GPIO.HIGH)
10.    elif range == 2:
11.        GPIO.output(range2, GPIO.HIGH)
```

Program code:  
[https://github.com/DYK-Team/QI-1\\_thruster](https://github.com/DYK-Team/QI-1_thruster)

Current sensor CS-1  
does not use  
multiplexing but in the  
function this option has  
been reserved.

# QI-2\_GUI. Run “UI.py”.

Run

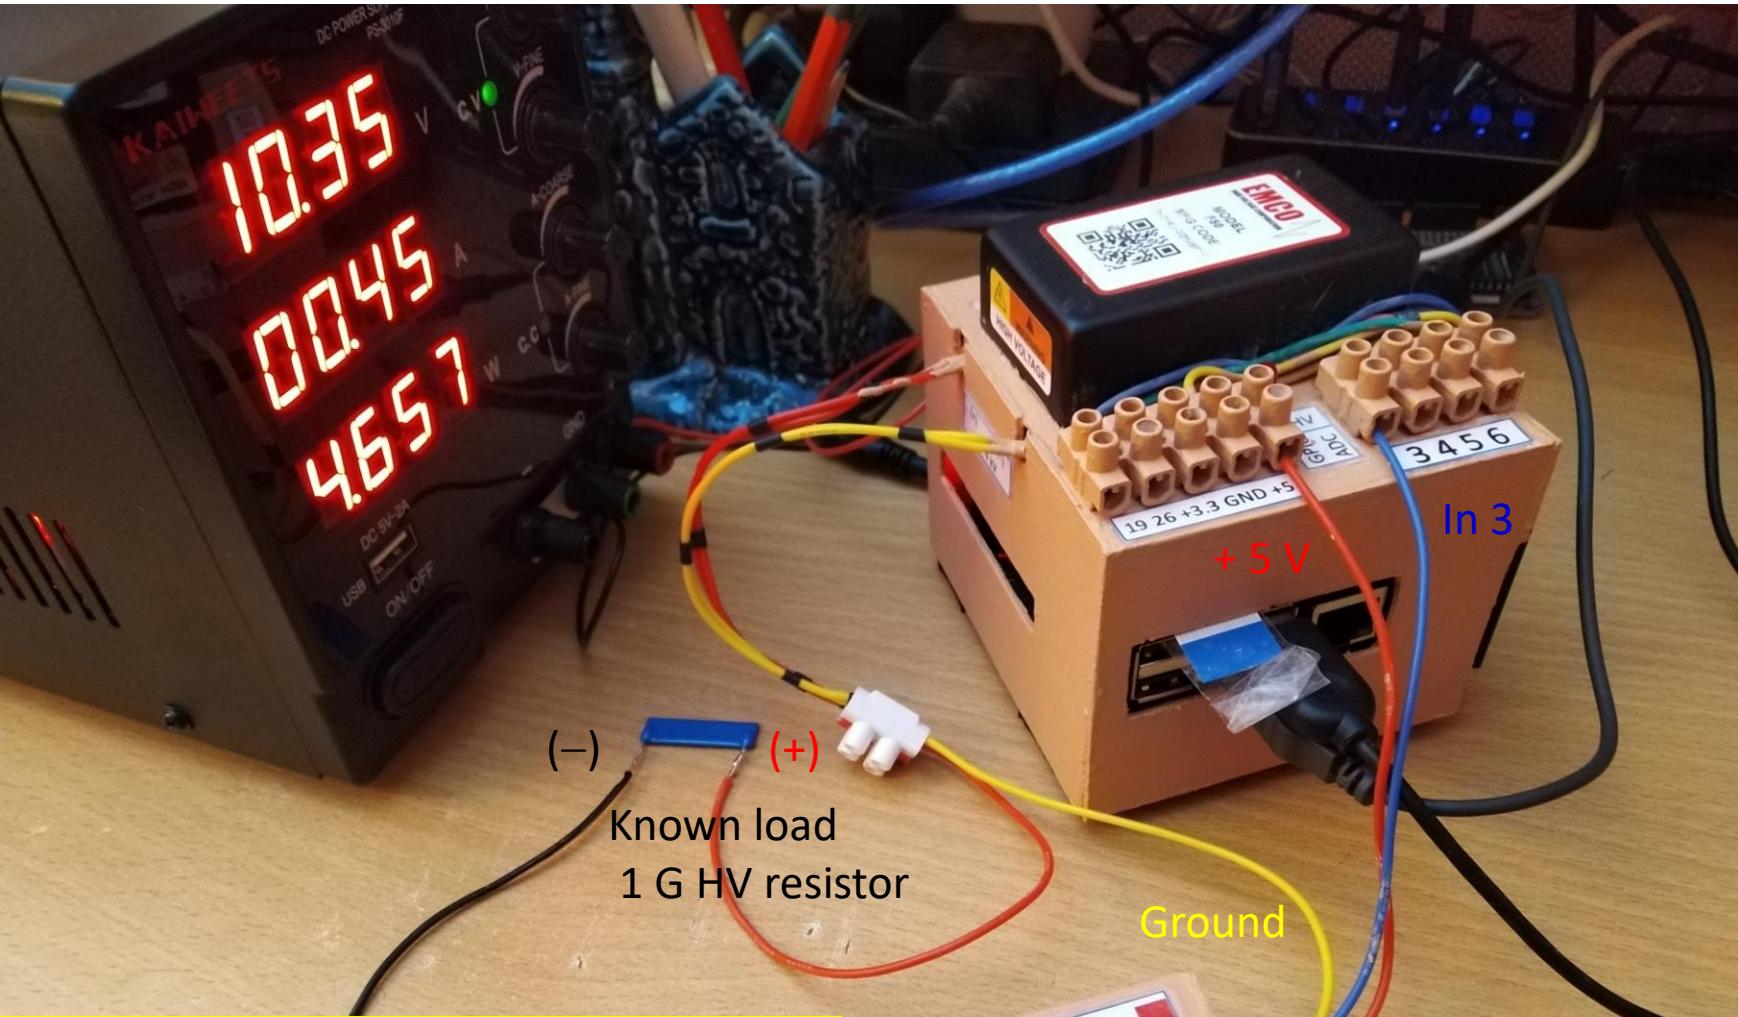

Program code:

[https://github.com/DYK-Team/QI-2\\_thruster\\_GUI](https://github.com/DYK-Team/QI-2_thruster_GUI)

Current sensor CS-1 does not use multiplexing but in the function this option has been reserved.

# Current sensor calibration: circuit

Our CS-1 current sensor showed an unexpected output voltage offset of about 1 V. Instead of finding out the cause of this offset at the electronics level, we decided to work around the problem with numerical calibration.

# Current sensor calibration: procedure

1. Connect a 1 G (1%) HV resistor instead of the QI capacitor as shown in the previous slide.
2. In the file “Functions.py”, modify the current function “CurrentSensor(bias, Ch)”, by uncommenting the line 6, see below. The function will return the x-value, not y.

```
1. def CurrentSensor(bias, Ch):  
2.     x = (Read_ADC(Ch) - bias)  
3.     y = -0.11372504497803 * x**8 + 1.4343168169319 * x**7 - 7.3278668065487 * x**6 + \  
4.         19.4325718360446 * x**5 - 28.448512253201 * x**4 + \  
5.         22.3174566367283 * x**3 - 7.6319260686742 * x**2 + 1.1951000922818 * x  
6.     #return x # used during the sensor calibration  
7.     return y
```

3. Run the program and increase the HV voltage output step by step (SHIFT button) up to the maximum value 4 kV. Put zero thrust after each step. The program will calculate the offset automatically (bias) and subtract it.
4. After achieving 4 kV, stop the program (ESC).
5. The program will create an output file with four columns: OP AMP output (V), HV output (kV), current sensor output (arb units during the calibration), and thrust (your units).
6. In Excel, draw the scatter graph “HV output” (y-axis) vs. “current sensor output” (x-axis).
  - a) Draw the trend line of this graph, choosing “polynomial” of the order 8 (RPI Office allows 8 and higher orders).
  - b) Visualise the equation of the polynomial.
  - c) Put the new polynomial coefficients into the function above.
7. Comment (#) the line 6 in the function “CurrentSensor(bias, Ch)” so that the function returns the y-value.
8. When you run the program again, the current units will be uA.
9. Leave the resistor connected and run the program again to check the calibration. You must obtain almost straight line with 1:1 correspondence between HV output (x-axis) and current sensor output (y-axis).

# Testing the device with a commercial capacitor

Capacitor is connected directly to the HV output

This configuration was chosen for loads with a very high internal resistance ( $G\Omega$ ), such as a capacitor before breakdown. If the load resistance drops to  $M\Omega$  or lower, the device will show **~zero HV voltage** (reading at ADC In 7), since all current will flow through the load, and not through the internal  $1 G\Omega$  resistor. That is, a  $M\Omega$  load will be like a short circuit for the internal voltmeter. **However, this configuration makes it possible to catch the moment of breakdown of the capacitor if the current through it is too large to be measured.**

Battery voltage = 13.797578431571639 V  
 Op Amp output = 3.422681863150877 V  
 Actual HV output = 2.0696453247543634 kV  
 Current through the capacitor = 0.08494084194500984 uA  
 Enter the thrust reading (any units) from

Battery voltage = 13.788830469729767 V  
 Op Amp output = 3.539873637976066 V  
 Actual HV output = 0.7246848594977916 kV  
 Current through the capacitor = -108.82935841017131 uA  
 Enter the thrust reading (any units) from the electronic scale:

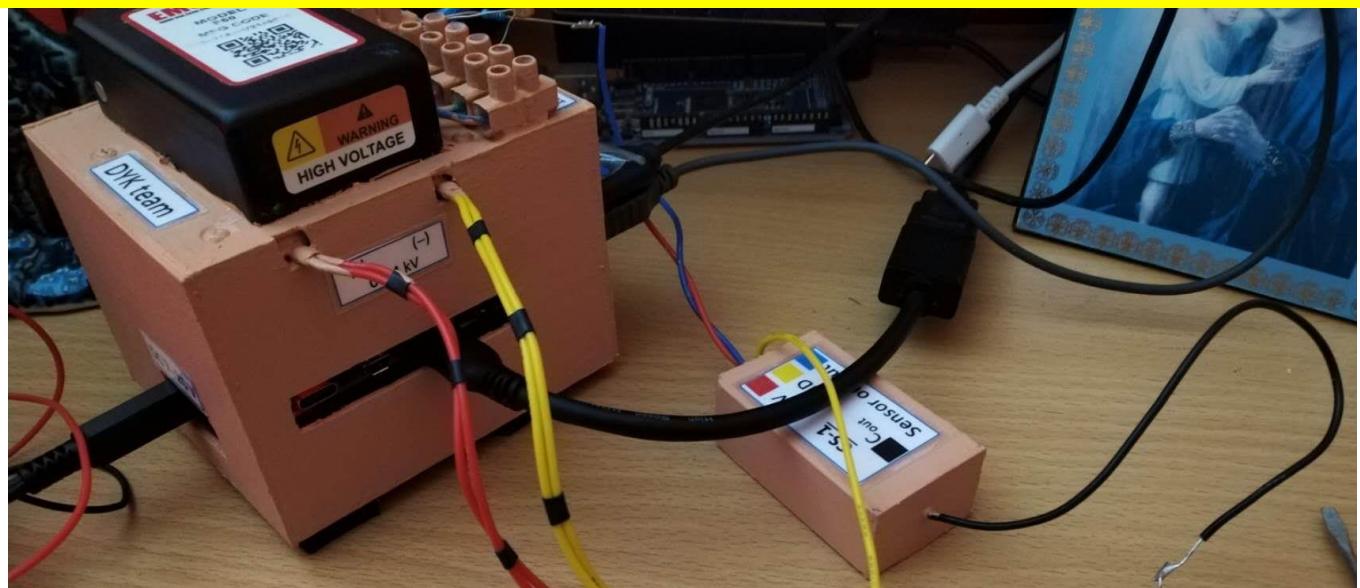

Sudden voltage drop during the capacitor breakdown

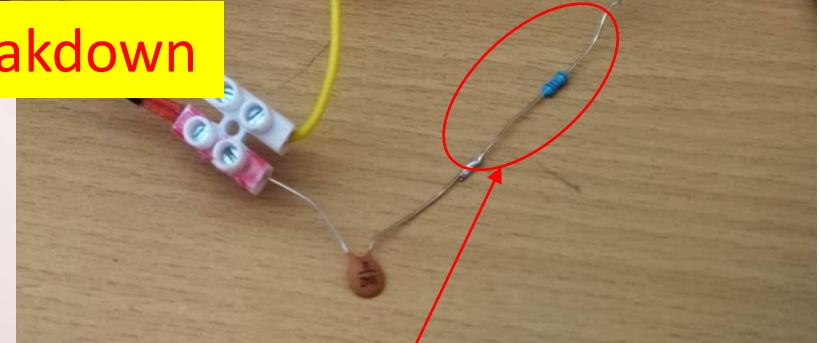

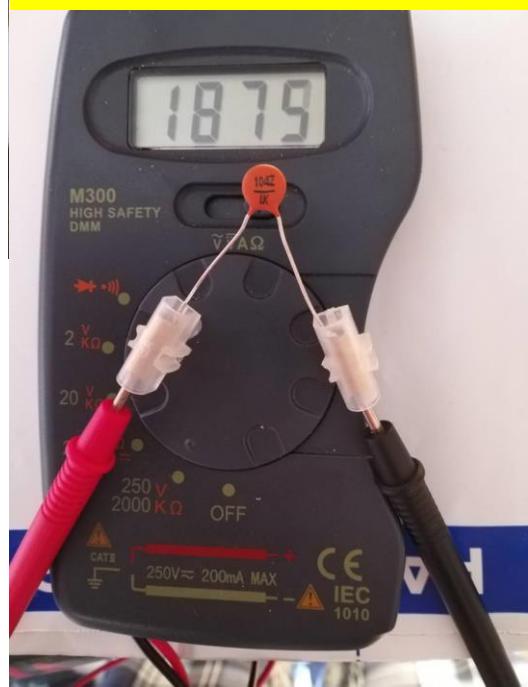

The character of breakdown may depend on the current through the capacitor and the type of dielectric.

98 k $\Omega$  after breakdown

1.879 M $\Omega$  after breakdown

Additional 1 M $\Omega$  series resistor + 1.5 M $\Omega$  resistor inside the current sensor

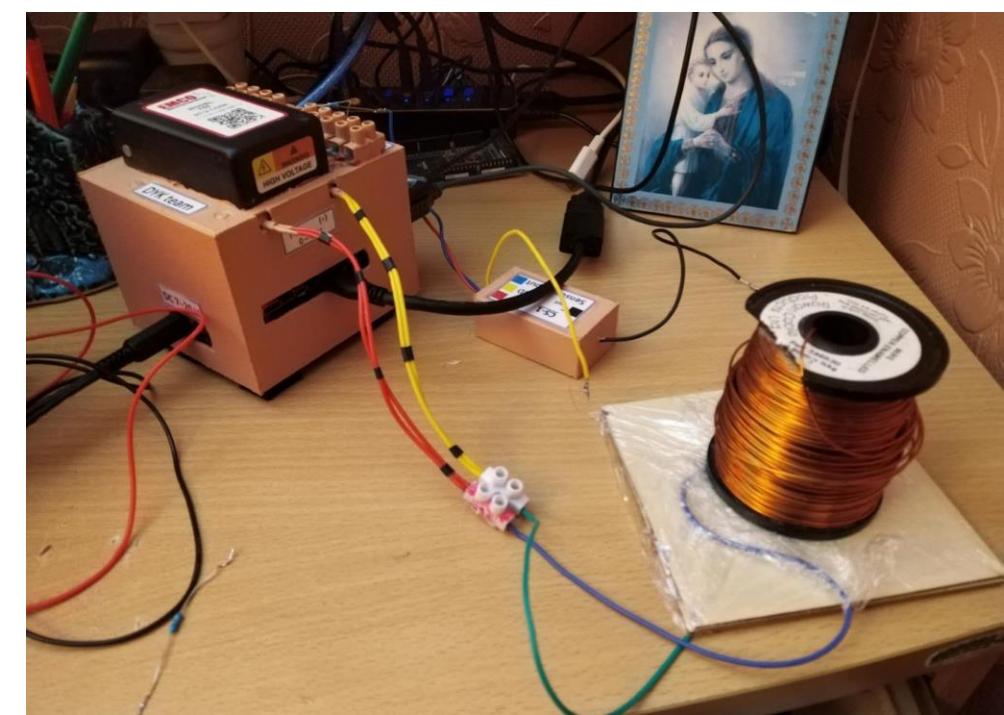

Wire end bundle for foil contact

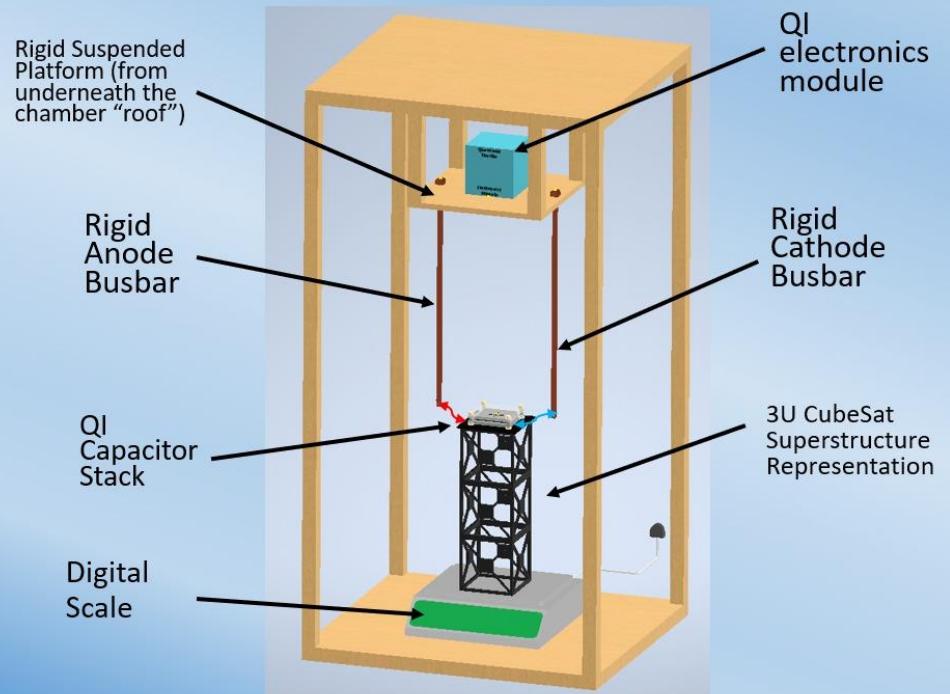

"QI Capacitor" testing: plywood pads, kitchen foil electrodes, and two layers of kitchen cling film. The capacitor was connected directly to the HV output without a current sensor. The first single discharges began at ~1.6 kV. This was followed by a series of discharges through 2 kV. **A series resistor (current conditions) may affect this scenario...** During discharges, ADC began to show errors, but Raspberry Pi did not collapse. Therefore, there was time to stop the process.

"Bullet" breakdown

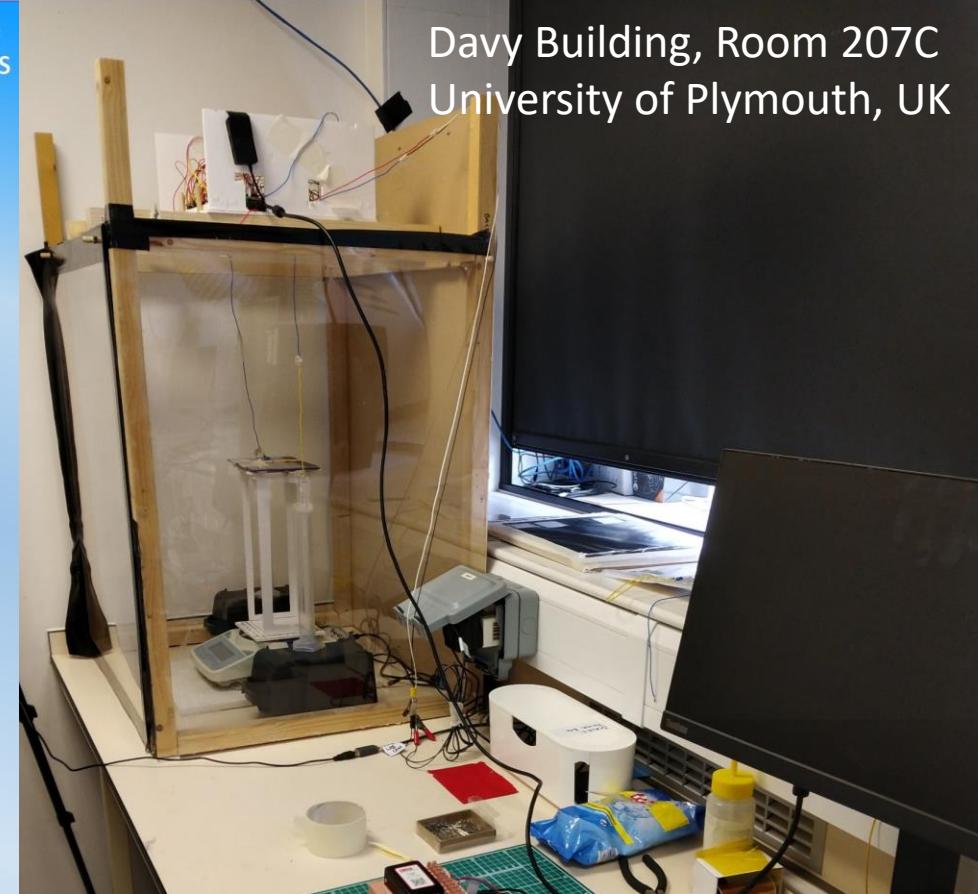

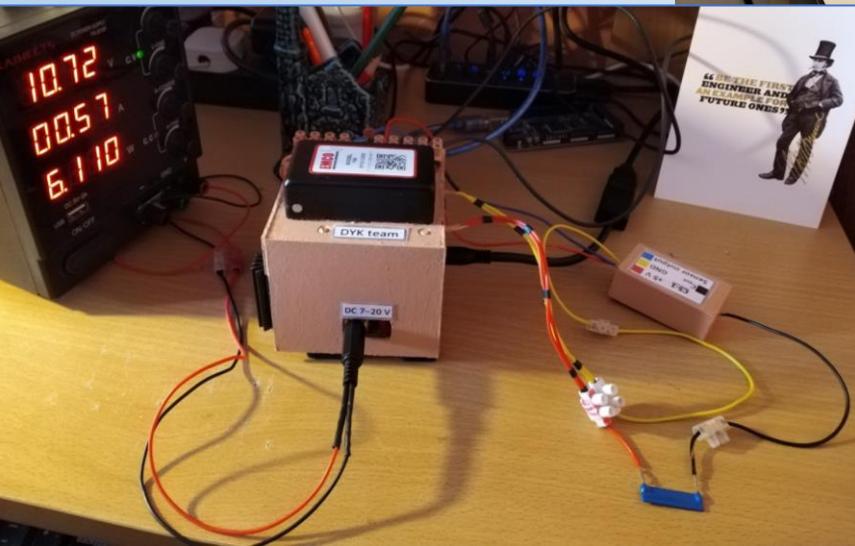

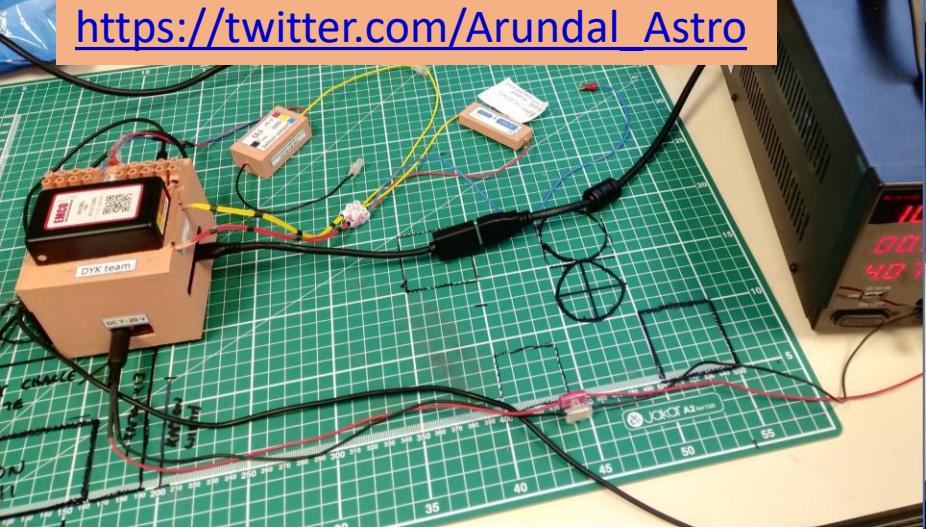

# QI Test Chamber V1 (Non Vacuum)

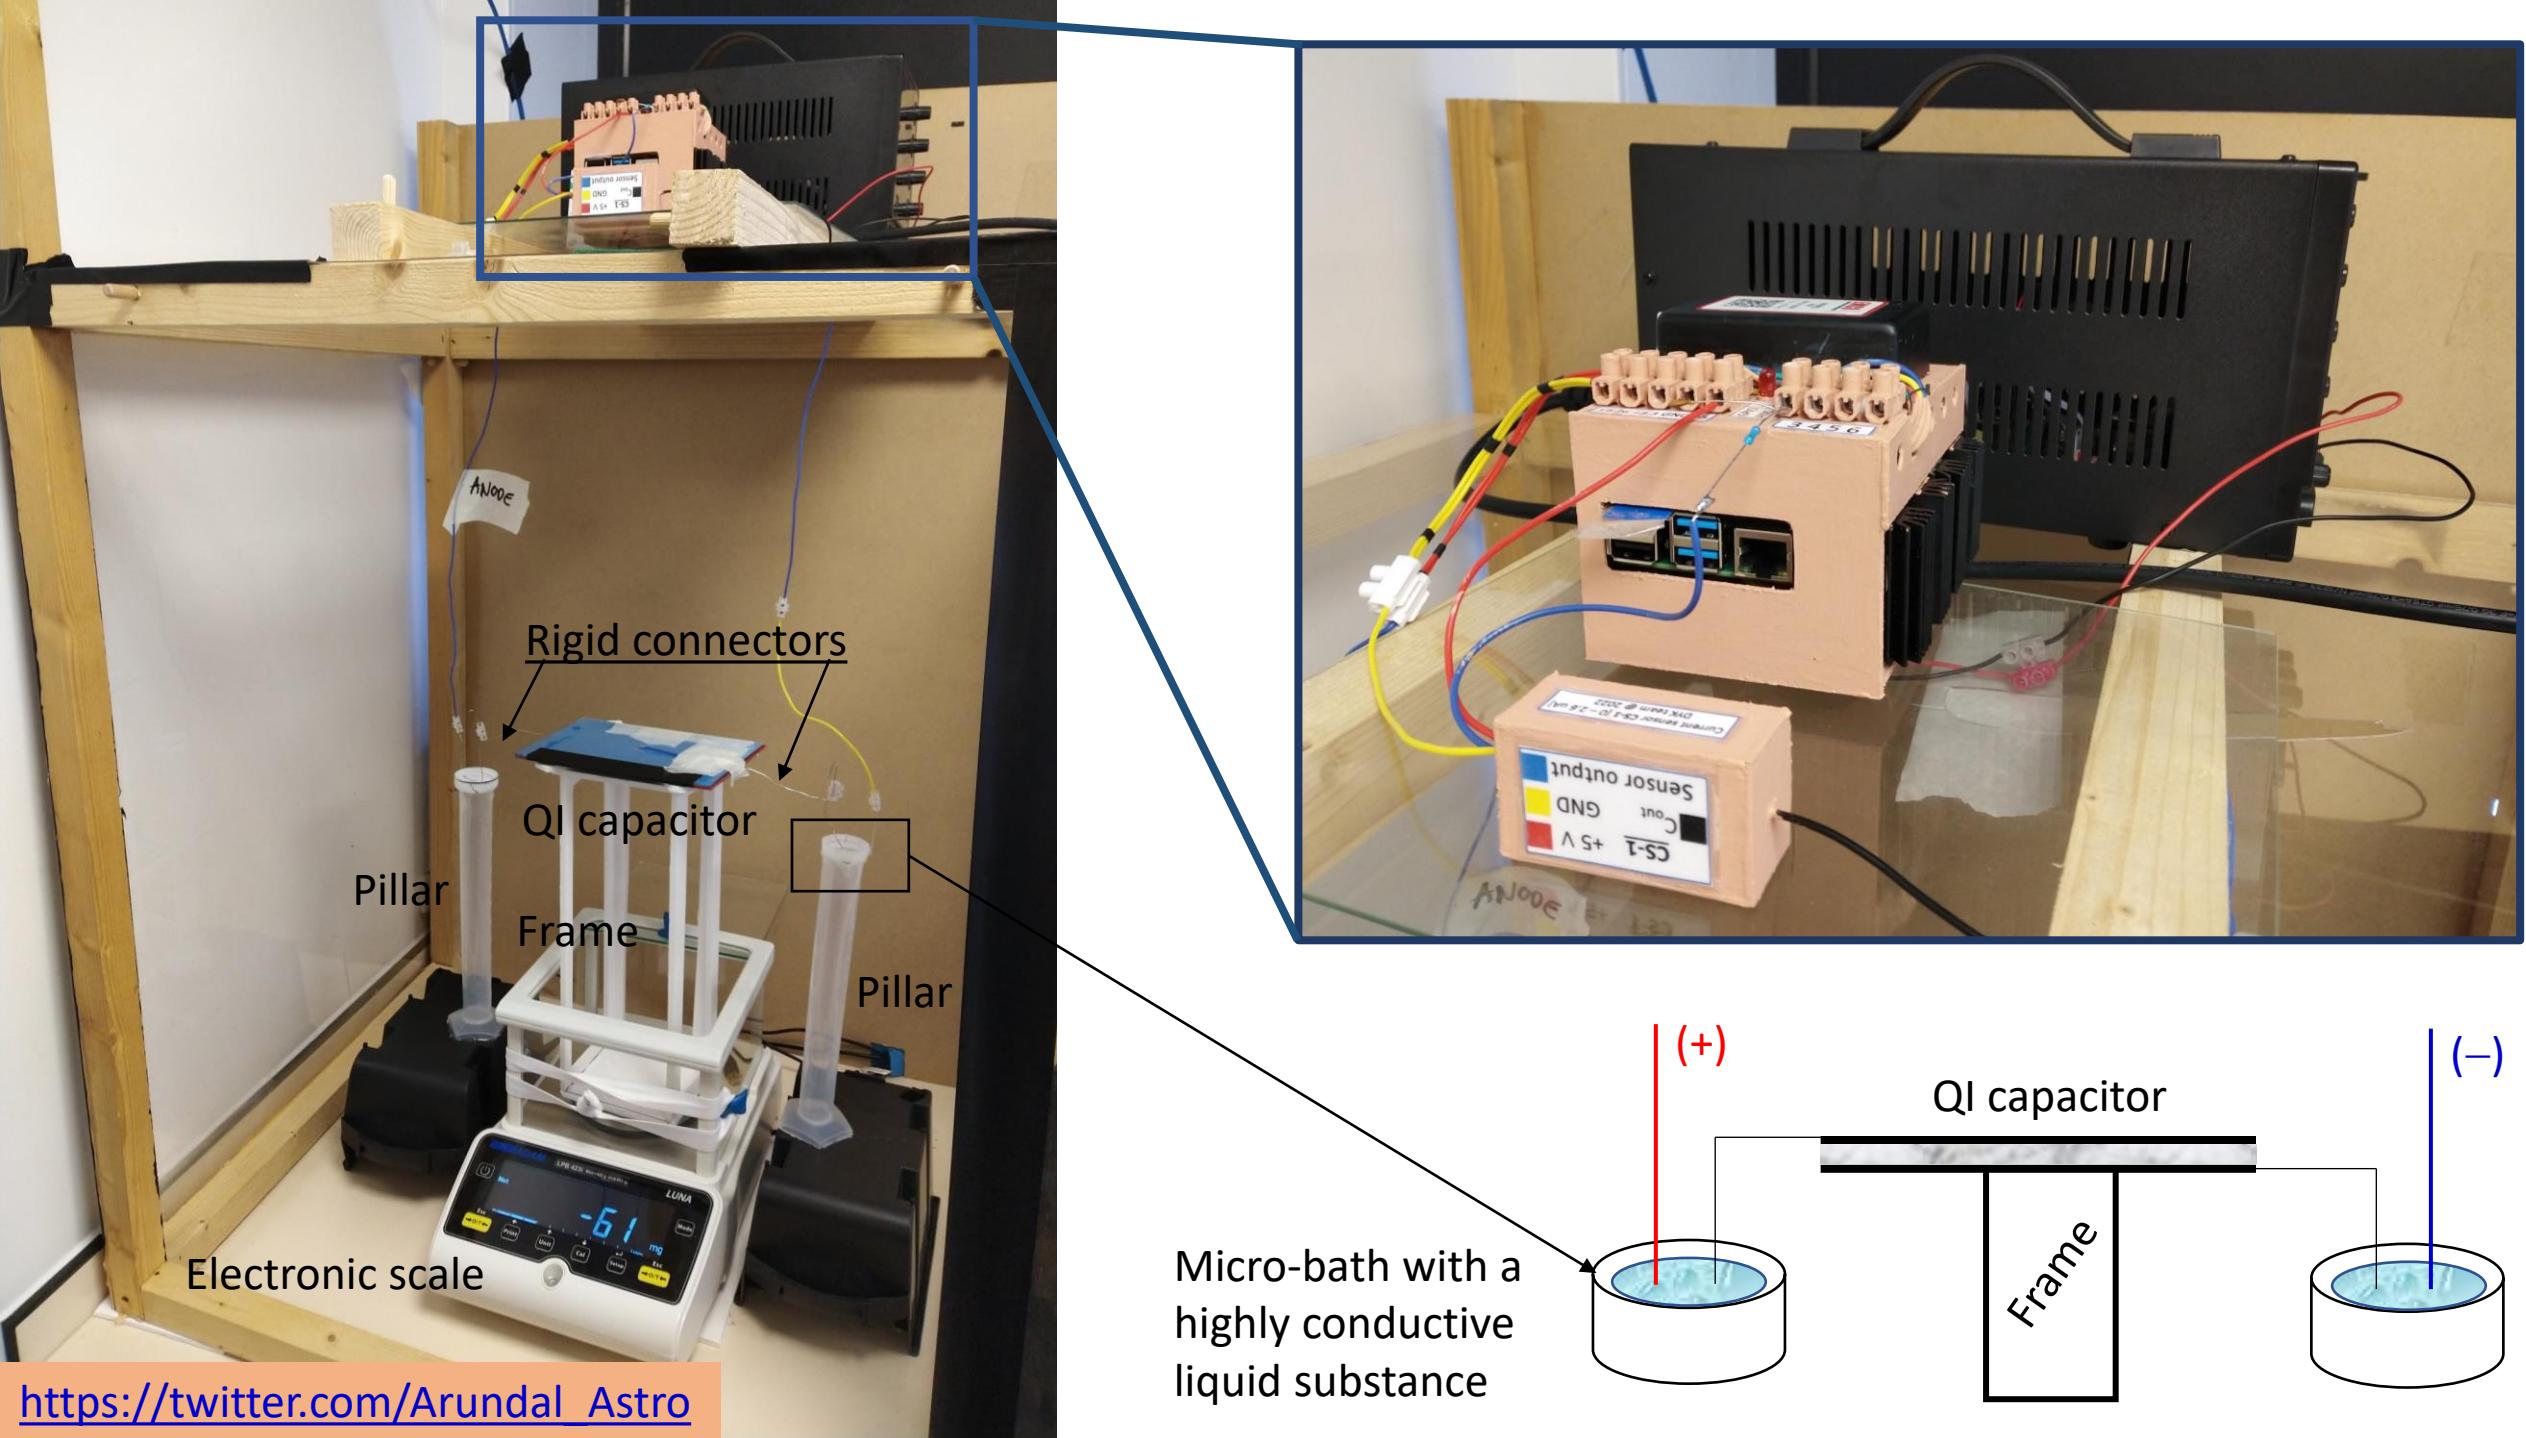

## Revised Quantised Inertia Test Chamber

- Wooden frame to avoid any undesired conduction
- Adjustable height Rigid bus bars suspended for anode / cathode conductors linked to the QI electronics module
  - End stage connectors using typical wires to link with the QI capacitor
- QI Capacitor rests upon 3U CubeSAT superstructure (and also to add distance from digital scale in case of electromagnetic interference)

Our design satisfies the CubeSat standards (<https://en.wikipedia.org/wiki/CubeSat>): a class of miniaturized satellite based around a form factor consisting of 10 cm (3.9 in) cubes. CubeSats have a mass of no more than 2 kg (4.4 lb) per unit, and often use commercial off-the-shelf (COTS) components for their electronics and structure.

An example of CubeSat design: “*New CubeSat propulsion system uses water as propellant*”  
<https://www.purdue.edu/newsroom/releases/2017/Q3/new-cubesat-propulsion-system-uses-water-as-propellant.html>
